A method to find generators of a semi-simple Lie group via the topology of its flag manifolds

Ariane Luzia dos Santos* Luiz A. B. San Martin‡

Abstract

In this paper we continue to develop the topological method started in Santos-San Martin [19] to get semigroup generators of semi-simple Lie groups. Consider a subset $\Gamma \subset G$ that contains a semi-simple subgroup G_1 of G. Then Γ generates G if $\mathrm{Ad}\,(\Gamma)$ generates a Zariski dense subgroup of the algebraic group $\mathrm{Ad}\,(G)$. The proof is reduced to check that some specific closed orbits of G_1 in the flag manifolds of G are not trivial in the sense of algebraic topology. Here, we consider three different cases of semi-simple Lie groups G and subgroups $G_1 \subset G$.

Key words and phrases: Semigroup generators of groups, semi-simple Lie groups, flag manifolds.

1 Introduction

In this paper we continue to develop the topological method started in Santos-San Martin [19] to get semigroup generators of semi-simple Lie groups.

The method is based on the notion of flag type of a semigroup that arouse from the results of [11], [12], [18], [13], [17], [14], [15] and [16]. By these results

if G is a connected noncompact semi-simple Lie group with finite center and $S \subset G$ is a proper semigroup with nonempty interior, then the flag type of S allows to select a flag manifold $\mathbb{F}_\Theta$ of G that contains a subset C_Θ (the so called invariant control set) which is invariant by S and is contained in an open Bruhat cell σ_Θ of $\mathbb{F}_\Theta$. Since σ_Θ is diffeomorphic to an Euclidean space $\mathbb{R}^N$ it follows that C_Θ is contractible in $\mathbb{F}_\Theta$.

Hence if one can show that a subset $\Gamma \subset G$ does not leave invariant a contractible subset on any flag manifold of G, then it is possible to conclude that Γ generates G if the semigroup generated by Γ has nonempty interior. Actually thanks to a result by Abels [1] this last condition can be changed by asking that $\mathrm{Ad}\,(\Gamma)$ generates a Zariski dense subgroup of the algebraic group $\mathrm{Ad}\,(G)$.

The problem of semigroup generation of groups has several motivations. One of them comes from control theory where the controllability problem is translated into the semigroup generation problem. Controllability results on semi-simple Lie groups where obtained in Jurdjevic-Kupka [9, 8], Gauthier-Kupka-Sallet [6] and El Assoudi-Gauthier-Kupka [3]. In another direction we mention the 1.5 generation problem studied in Abels [1], Abels-Vinberg [2] and references therein, which consists in finding pairs of generators starting from one element of the pair.

Here, as in our previous paper [19], we take as generator a subset $\Gamma \subset G$ that contains a semi-simple subgroup G_1 of G. In this setting the problem is reduced to check that some specific closed orbits of G_1 in the flag manifolds of G are not trivial in the sense of algebraic topology (see Proposition 3.2 below).

In [19] we pursued this approach with an eye in the controllability results mentioned above. Thus in [19] the group G is a connected complex simple Lie group and G_1 is a subgroup $G\,(\alpha)$ with Lie algebra isomorphic to $\mathfrak{sl}\,(2,\mathbb{C})$ generated by the root spaces $\mathfrak{g}_{\pm\alpha}$ associated to the roots $\pm\alpha$ of the complex Lie algebra $\mathfrak{g}$ of G. In that case the method was successfully applied because the relevant orbits of $G_1 = G\,(\alpha)$ are flag manifolds of $\mathfrak{sl}\,(2,\mathbb{C})$ so that diffeomorphic to S^2. We used De Rham cohomology $H^2\,(\mathbb{F}_\Theta,\mathbb{R})$ to prove that these orbits are not homotopic to a point for any flag manifold $\mathbb{F}_\Theta$.

In this paper we consider three different cases of semi-simple Lie groups G and subgroups $G_1 \subset G$.

In the first one we take G whose Lie algebra $\mathfrak{g}$ is the split real form of a complex simple Lie algebra and $G_1 = G\,(\alpha)$ is a subgroup generated by root spaces analogous to the complex case. In the real case we are led to check whether some closed curves are null homotopic and hence work with the fundamental groups of the flag manifolds. Contrary to the complex Lie algebras there are only a few cases where the relevant orbits of $G_1 = G(\alpha)$ are null homotopic. Namely when $\mathfrak{g} = \mathfrak{sl}(n, \mathbb{R})$, $\mathfrak{g} = \mathfrak{sp}(n, \mathbb{R})$ and α is a long root and when $\mathfrak{g}$ is the split real form of G_2 and α is a short root. In these cases the subgroups $G(\alpha)$ are not contained in proper semigroups with interior points and a subset Γ generates G if $G(\alpha) \subset \Gamma$ (any root α) and the group generated by Γ is Zariski dense (see Theorem 4.13 below). In the remaining cases our method breaks down. We give an example of a proper semigroup with nonempty interior in $\mathrm{Sp}(n, \mathbb{R})$ that contains $G(\alpha)$ for several short roots α, showing that the result is indeed not true in this case.

In another direction we take an irreducible finite dimensional representation $\rho_n : \mathfrak{sl}(2, \mathbb{C}) \to \mathfrak{sl}(n, \mathbb{C})$, $n \geq 2$, and get a subgroup $G_1 = \langle \exp \rho_n (\mathfrak{sl}(2, \mathbb{C})) \rangle \subset \mathrm{Sl}(n, \mathbb{C})$. We prove that G_1 is not contained in any proper semigroup with nonempty interior of $\mathrm{Sl}(n, \mathbb{C})$. It follows that a subset Γ is a semigroup generator of $\mathrm{Sl}(n, \mathbb{C})$ if it contains $\langle \exp \rho_n (\mathfrak{sl}(2, \mathbb{C})) \rangle$ and the group generated by Γ is Zariski dense (see Theorem 5.1). The algebraic topological fact that permits the proof of this result is Proposition 5.2. It shows that the projective orbit $G_1 \cdot [v_0]$ of the highest weight space is not contractible in the projective space of the vector space of the representation. This noncontractibility follows from the fact that the

tautological bundle of the projective space restricts to a nontrivial bundle on the orbit

In our third case we take a complex Lie group G and a complex subgroup G_1 such that the Lie algebra $\mathfrak{g}_1$ of G_1 contains a regular real element of the Lie algebra $\mathfrak{g}$ of G. Examples of this case are the inclusion in $\mathfrak{sl}(n, \mathbb{C})$ of the classical Lie algebras $B_l = \mathfrak{so}(2l+1, \mathbb{C})$, $C_l = \mathfrak{sp}(2l, \mathbb{C})$ and $D_l = \mathfrak{so}(2l, \mathbb{C})$. In this case we prove that G_1 is not contained in a proper semigroup with nonempty interior of G and hence get generators of G in the same spirit of the other cases (see Theorem 6.1). Here we exploit the same technique provided by Proposition 5.2 by realizing the flag manifolds of G as projective orbits in spaces of representations. The proof is not much different from the case of representations of $\mathfrak{sl}(2, \mathbb{C})$.

2 Notation and background

Let G be a connected real semi-simple Lie group with finite center and Lie algebra $\mathfrak{g}$. For G and $\mathfrak{g}$ we use the following notation.

- Let θ be a Cartan involution of $\mathfrak{g}$ and $\mathfrak{g} = \mathfrak{k} \oplus \mathfrak{s}$ the corresponding Cartan decomposition.
- If $\mathfrak{a} \subset \mathfrak{s}$ is a maximal abelian subalgebra its set of roots is denoted by Π. Let Π^+ be a set of positive roots with

  $$\Sigma = \{\alpha_1, \dots, \alpha_l\} \subset \Pi^+$$

  corresponding simple system of roots. We have $\Pi = \Pi^+ \dot{\cup} (-\Pi^+)$ and any $\alpha \in \Pi^+$ is a linear combination $\alpha = n_1\alpha_1 + \cdots + n_l\alpha_l$ and $n_i \geq 0$, $i = 1, \dots, l$ are integers. The support of α, $\mathrm{supp}\alpha$, is the subset of Σ where $n_i > 0$.
- The Cartan-Killing form of $\mathfrak{g}$ is denoted by $\langle \cdot, \cdot \rangle$. If $\alpha \in \mathfrak{a}^*$ then $H_\alpha \in \mathfrak{a}$ is defined by $\alpha(\cdot) = \langle H_\alpha, \cdot \rangle$, and $\langle \alpha, \beta \rangle = \langle H_\alpha, H_\beta \rangle$.
- We write

  $$\mathfrak{a}^+ = \{H \in \mathfrak{a} : \forall \alpha \in \Pi^+,\, \alpha(H) > 0\}$$

  for the Weyl chamber defined by Π^+.
- The root space of a root α is

  $$\mathfrak{g}_\alpha = \{X \in \mathfrak{g} : \forall H \in \mathfrak{a},\, [H, X] = \alpha(H)X\}.$$

  If $\mathfrak{g}$ is a split real form of a complex simple Lie algebra then $\dim_{\mathbb{R}} \mathfrak{g}_\alpha = 1$.
- For a root α, $\mathfrak{g}(\alpha)$ is the subalgebra generated by $\mathfrak{g}_\alpha$ and $\mathfrak{g}_{-\alpha}$. We have

  $$\mathfrak{g}(\alpha) = \mathrm{span}_{\mathbb{R}}\{H_\alpha\} \oplus \mathfrak{g}_\alpha \oplus \mathfrak{g}_{-\alpha} \approx \mathfrak{sl}(2, \mathbb{R}).$$

  We let $G(\alpha)$ be the connected Lie subgroup of G with Lie algebra $\mathfrak{g}(\alpha)$.
- Let $K = \langle \exp \mathfrak{k} \rangle$ be the maximal compact subgroup of G with Lie algebra $\mathfrak{k}$.

- $\mathcal{W}$ is the Weyl group. Either $\mathcal{W}$ is the group generated by the reflections r_α, $\alpha \in \Pi$, $r_\alpha(\beta) = \beta - \frac{2\langle \alpha, \beta \rangle}{\langle \alpha, \alpha \rangle}\alpha$, or $\mathcal{W} = M^*/M$ where $M^* = \mathrm{Norm}_K(\mathfrak{a})$ is the normalizer of $\mathfrak{a}$ in K and $M = \{g \in K : \mathrm{Ad}(g)H = H \text{ for all } H \in \mathfrak{h}\}$ is the centralizer of $\mathfrak{a}$ in K.

- $\mathfrak{n}^+ = \sum_{\alpha \in \Pi^+} \mathfrak{g}_\alpha$ and $\mathfrak{n}^- = \sum_{\alpha \in \Pi^+} \mathfrak{g}_{-\alpha}$.

- Given the data $\mathfrak{a}$ and Π^+ (or Σ) there exists the minimal parabolic subalgebra $\mathfrak{p} = \mathfrak{m} \oplus \mathfrak{a} \oplus \mathfrak{n}^+$. A subset $\Theta \subset \Sigma$ defines the standard parabolic subalgebra by

  $$\mathfrak{p}_\Theta = \mathfrak{p} + \sum_{\alpha \in \langle \Theta \rangle} \mathfrak{g}_\alpha$$

  where $\langle \Theta \rangle = \{\alpha \in \Pi : \mathrm{supp}\alpha \subset \Theta \text{ or } \mathrm{supp}(-\alpha) \subset \Theta\}$ is the set of roots spanned by Θ. When $\Theta = \emptyset$ we have $\mathfrak{p}_\emptyset = \mathfrak{p}$.

- For $\Theta \subset \Sigma$, P_Θ is the parabolic subgroup with Lie algebra $\mathfrak{p}_\Theta$:

  $$P_\Theta = \mathrm{Norm}_G(\mathfrak{p}_\Theta) = \{g \in G : \mathrm{Ad}(g)\mathfrak{p}_\Theta \subset \mathfrak{p}_\Theta\}.$$

- The flag manifold $\mathbb{F}_\Theta = G/P_\Theta$ does not depend on the specific group G with Lie algebra $\mathfrak{g}$. The origin of G/P_Θ, the coset $1 \cdot P_\Theta$, is denoted by b_Θ.

Now let $S \subset G$ be a subsemigroup with $\mathrm{int}S \neq \emptyset$. We recall some results of [12, 18, 17] that are on the basis of our topological approach to get generators of G.

We let S act on a flag manifold $\mathbb{F}_\Theta$ by restricting the action of G. An invariant control set for S in $\mathbb{F}_\Theta$ is a subset $C \subset \mathbb{F}_\Theta$ such that $\mathrm{cl}(Sx) = C$ for every $x \in C$, where $Sx = \{gx \in \mathbb{F}_\Theta : g \in S\}$. Since $\mathrm{int}S \neq \emptyset$ such a set is closed, has nonempty interior and is in fact invariant, that is, $gx \in C$ if $g \in S$ and $x \in C$.

Lemma 2.1 *([12, Theorem 3.1]) In any flag manifold F_Θ there is a unique invariant control set for S, denoted by C_Θ.*

To state the geometric property of C_Θ to be used later we discuss the dynamics of the vector fields $\widetilde{H}$ on a flag manifold $\mathbb{F}_\Theta$ whose flow is e^{tH}, with H in the closure $\mathrm{cl}\mathfrak{a}^+$ of the Weyl chamber $\mathfrak{a}^+$. It is known that $\widetilde{H}$ is a gradient vector field with respect to some Riemmannian metric on $\mathbb{F}_\Theta$; cf. [4, Proposition 3.3 (ii)] and [5].

Hence the orbits of $\widetilde{H}$ are either fixed points of e^{tH} or trajectories flowing between fixed points of H. Moreover, $\widetilde{H}$ has a unique attractor fixed point set, say $\mathrm{att}_\Theta(H)$, that has an open and dense stable manifold $\sigma_\Theta(H)$; cf. [4, 5]. This means that if $x \in \sigma_\Theta(H)$ then its ω-limit set $\omega(x)$ is contained in $\mathrm{att}_\Theta(H)$. This attractor has the following algebraic expressions

$$\mathrm{att}_\Theta(H) = Z_H \cdot b_\Theta = K_H \cdot b_\Theta,$$

cf. [4, Corollary 3.5] and [5]. Here $Z_H = \{g \in G : \mathrm{Ad}(g)H = H\}$ is the centralizer of H in G and $K_H = Z_H \cap K$ is the centralizer in K. We note that $\mathrm{att}_\Theta(H)$ is a connected manifold because $Z_H = M(Z_H)_0 = (Z_H)_0 M$ where $(Z_H)_0$ is the identity component of Z_H and M is the centralizer of $\mathfrak{a}$ in K; see [20, Lemma 1.2.4.5]. Hence $Z_H \cdot b_\Theta = (Z_H)_0 \cdot b_\Theta$, since $M \cdot b_\Theta = b_\Theta$; cf. [10, Theorem 7.101].

The stable set $\sigma_\Theta(H)$ is also described algebraically by

$$\sigma_\Theta(H) = N_H^- Z_H \cdot b_\Theta$$

where

$$N_H^- = \exp \mathfrak{n}_H^- \quad \text{and} \quad \mathfrak{n}_H^- = \sum_{\gamma(H)<0} \mathfrak{g}_\gamma,$$

cf. [4, Corollary 3.5]. In particular if H is regular, that is, $H \in \mathfrak{a}$ and $\alpha(H) > 0$ for $\alpha \in \Pi^+$, then $Z_H = MA$, which fixes b_Θ. Hence

$$\mathrm{att}_\Theta(H) = Z_H \cdot b_\Theta = \{b_\Theta\} \qquad H \in \mathfrak{a}.$$

Actually, in the regular case the fixed points are isolated because $\widetilde{H}$ is the gradient of a Morse function; cf. [4, 5]. Also, $\mathfrak{n}_H^- = \mathfrak{n}^-$ (notation as above) and the stable set is $N^- \cdot b_\Theta$ the open Bruhat cell.

The following statement is a well known result from the Bruhat decomposition of the flag manifolds; cf. [4, 10, 20].

Proposition 2.2 *In any flag manifold $\mathbb{F}_\Theta$ the open Bruhat cell $N^- \cdot b_\Theta$ is diffeomorphic to an Euclidean space $\mathbb{R}^d$. The diffeomorphism is $X \in \mathfrak{n}_\Theta^- \mapsto e^X \cdot b_\Theta$, where $\mathfrak{n}_\Theta^- = \sum\{\mathfrak{g}_\alpha : \alpha < 0$ and $\alpha \notin \langle\Theta\rangle\}$.*

Set $h = e^H$, $H \in \mathfrak{a}^+$. It follows from the gradient property of $\widetilde{H}$ that $\lim_{n\to+\infty} h^n x = b_\Theta$ for any $x \in N^- \cdot b_\Theta$.

Now, we say that $g \in G$ is regular real if it is a conjugate $g = aha^{-1}$ of $h = \exp H$, $H \in \mathfrak{a}^+$ with $a \in G$. Then we write $\sigma_\Theta(g) = g \cdot \sigma_\Theta(H)$ and we call this the stable set of g in $\mathbb{F}_\Theta$. The reason for this name is clear: $g^n = (aha^{-1})^n = ah^n a^{-1}$ and hence $g^n x \to gb_\Theta$ if $x \in \sigma_\Theta(g)$.

The following lemma was used in [12] to prove the above Lemma 2.1.

Lemma 2.3 *([12, Lemma 3.2]) There exists a regular real $g \in \mathrm{int}S$.*

Now we can state the following result of [17] which is basic to our approach.

Theorem 2.4 *Suppose that $S \neq G$. Then there exists a flag manifold $\mathbb{F}_\Theta$ such that the invariant control set $C_\Theta \subset \sigma_\Theta(g)$ for every regular real $g \in \mathrm{int}S$.*

Corollary 2.5 *If $S \neq G$ then there exists a flag manifold $\mathbb{F}_\Theta$ such that for every flag manifold $\mathbb{F}_{\Theta_1}$ such that $\Theta \subset \Theta_1$ the invariant control set C_{Θ_1} in $\mathbb{F}_{\Theta_1}$ is contained in a subset $\mathcal{E}_{\Theta_1}$ diffeomorphic to an Euclidean space.*

Proof. If $\Theta_1 \subset \Theta$ then the canonical projection $\pi : \mathbb{F}_\Theta \to \mathbb{F}_{\Theta_1}$ is equivariant under the actions of G. This implies that the open Bruhat cells are projected onto open cells and $\pi(C_\Theta) = C_{\Theta_1}$. Hence C_{Θ_1} is contained in an open cell $\mathcal{E}_{\Theta_1}$ if this happens to C_Θ. $\square$

In particular if $\Theta_1 = \Sigma \setminus \{\alpha\}$ contains Θ if $\alpha \in \Sigma \setminus \Theta$ so in the minimal flag manifold $\mathbb{F}_{\Sigma\setminus\{\alpha\}}$ the invariant control set is contained in open cells.

Corollary 2.6 *If $S \neq G$ then there exists a minimal flag manifold $\mathbb{F}_\Theta$ such that C_Θ is contained in a subset $\mathcal{E}_\Theta$ diffeomorphic to an Euclidean space.*

Remark: It can be proved that there exists a minimal $\Theta(S)$ satisfying the condition of Theorem 2.4. This $\Theta(S)$ (or rather the flag manifold $\mathbb{F}_{\Theta(S)}$) is called the flag type or parabolic type of S. Several properties of S are derived from this flag type, e.g. the homotopy type of S as in [16] or the connected components of S as in [11].

3 Semi-simple subgroups: Set up

Let $\mathfrak{g}$ be a noncompact semi-simple Lie algebra and G be a connected Lie group with Lie algebra $\mathfrak{g}$ and finite center. In this section we take a semi-simple subalgebra $\mathfrak{g}_1 \subset \mathfrak{g}$ and the corresponding connected subgroup $G_1 = \langle \exp \mathfrak{g}_1 \rangle$. We ask whether there is a proper semigroup $S \subset G$ with $\mathrm{int} S \neq \emptyset$ such that $G_1 \subset S$.

It is well known that there exist compatible Cartan decompositions $\mathfrak{g}_1 = \mathfrak{k}_1 \oplus \mathfrak{s}_1$ and $\mathfrak{g} = \mathfrak{k} \oplus \mathfrak{s}$ such that $\mathfrak{k}_1 \subset \mathfrak{k}$ and $\mathfrak{s}_1 \subset \mathfrak{s}$ (see Warner [20, Lemma 1.1.5.5]). If $\mathfrak{a}_1 \subset \mathfrak{s}_1$ is maximal abelian then there exists a maximal abelian $\mathfrak{a} \subset \mathfrak{s}$ with $\mathfrak{a}_1 \subset \mathfrak{a}$. Denote by Π_1 the roots of $(\mathfrak{g}_1, \mathfrak{a}_1)$ and by Π the roots of $(\mathfrak{g}, \mathfrak{a})$. Any $\alpha_1 \in \Pi_1$ is the restriction to $\mathfrak{a}_1$ of some $\alpha \in \Pi$. Take $H_1 \in \mathfrak{a}_1$ regular (in $\mathfrak{g}_1$). Then there exists a Weyl chamber $\mathfrak{a}^+ \subset \mathfrak{a}$ with $H_1 \in \mathrm{cl}\mathfrak{a}^+$. If $\alpha \in \Pi$ is positive w.r.t $\mathfrak{a}^+$ then $\alpha(H_1) \geq 0$ so that we get compatible Iwasawa decompositions $\mathfrak{g}_1 = \mathfrak{k}_1 \oplus \mathfrak{a}_1 \oplus \mathfrak{n}_1$ and $\mathfrak{g} = \mathfrak{k} \oplus \mathfrak{a} \oplus \mathfrak{n}$ with $\mathfrak{k}_1 \subset \mathfrak{k}$, $\mathfrak{a}_1 \subset \mathfrak{a}$ and $\mathfrak{n}_1 \subset \mathfrak{n}$ where

$$\mathfrak{n}_1 = \sum_{\alpha_1 \in \Pi_1^+} (\mathfrak{g}_1)_{\alpha_1}, \quad \mathfrak{n} = \sum_{\alpha \in \Pi^+} \mathfrak{g}_\alpha$$

and Π_1^+ is the set of roots of $(\mathfrak{g}_1, \mathfrak{a}_1)$ that are positive on H_1 and Π^+ the roots positive on $\mathfrak{a}^+$.

In the sequel we keep fixed these compatible Iwasawa decompositions. Let Σ be the simple system of roots in Π^+. Then the standard parabolic subalgebras $\mathfrak{p}_\Theta \subset \mathfrak{g}$ and subgroups $P_\Theta \subset G$ are built from subsets $\Theta \subset \Sigma$. For the corresponding flag manifolds $\mathbb{F}_\Theta = G/P_\Theta$ we write $b_\Theta = 1 \cdot P_\Theta$ for their origins.

By the construction of the compatible Iwasawa decomposition from the choice of $H_1 \in \mathfrak{a}_1 \cap \mathrm{cl}\mathfrak{a}^+$ we have that b_Θ belongs to the attractor fixed point set $\mathrm{att}_\Theta(H_1) = Z_{H_1} \cdot b_\Theta = K_{H_1} \cdot b_\Theta$ of the one-parameter semigroup e^{tH_1}, $t \geq 0$. The corresponding stable set $\sigma_\Theta(H_1)$ is open and dense in $\mathbb{F}_\Theta$.

Now let S be a semigroup with $\mathrm{int} S \neq \emptyset$ such that $G_1 \subset S$. Denote by C_Θ the unique S-invariant control set in $\mathbb{F}_\Theta$. The set C_Θ is compact and has nonempty interior. Hence $C_\Theta \cap \sigma_\Theta(H_\alpha) \neq \emptyset$. If $x \in C_\Theta \cap \sigma_\Theta(H_\alpha)$ then $y = \lim_{t \to +\infty} e^{tH_\alpha} \cdot x$ belongs to $C_\Theta \cap \mathrm{att}_\Theta(H_\alpha)$, because C_Θ is closed. Hence we get the following lemma.

Lemma 3.1 *If $G_1 \subset S$ then $C_\Theta \cap \mathrm{att}_\Theta(H_1) \neq \emptyset$.*

Now the idea is to look at the topology of the orbits $G_1 \cdot y$ with $y \in \mathrm{att}_\Theta(H_1)$. Clearly if $y \in C_\Theta$ and $G_1 \subset S$ then $G_1 \cdot y \subset C_\Theta$. On the other hand, by Theorem 2.4 and its corollaries, there are flag manifolds where C_Θ is contained in a contractible Euclidean subset $\mathcal{E}_\Theta$ if S is proper. Hence if we achieve to prove that none of the orbits $G_1 \cdot y$ with $y \in \mathrm{att}_\Theta(H_1)$ are contractible then we can conclude that G_1 is not contained in a proper semigroup with nonempty interior. In principle this noncontractibility property must by checked on every flag manifold but by Corollary 2.6 it is enough to look at the minimal ones.

These arguments can be used to get semigrouop generators of G. In fact, if Γ is a subset that contains G_1 and generates a semigroup S with nonempty interior then $S = G$ provided we have noncontractibility of the orbits $G_1 \cdot y$ through the attractor fixed point set.

Actually, thanks to a result by Abels [1] it is enough to assume that the group generated by Γ is Zariski dense in the following sense: The group $\mathrm{Ad}\,(G)$ is algebraic and hence endowed with the Zariski topology. We say that $B \subset G$ is Zariski dense in case $\mathrm{Ad}\,(B)$ is dense in $\mathrm{Ad}\,(G)$ with respect to the Zariski topology. With this terminology it is proved in [1], as a consequence of Corollary 5, that the semigroup S generated by Γ has non empty interior provided i) the group generated by Γ is Zariski dense and ii) S contains a non-constant smooth curve.

These comments yield the following fact that reduces the problem of finding semigroup generators to the topology of orbits of G_1.

Proposition 3.2 *Let $\mathfrak{g}_1 \subset \mathfrak{g}$ be a semi-simple Lie subalgebra. Choose compatible Iwasawa decompositions $\mathfrak{g}_1 = \mathfrak{k}_1 \oplus \mathfrak{a}_1 \oplus \mathfrak{n}_1 \subset \mathfrak{g} = \mathfrak{k} \oplus \mathfrak{a} \oplus \mathfrak{n}$, so that $\mathrm{cl}\mathfrak{a}^+$ contains a regular element $H_1 \in \mathfrak{a}_1$. Let $G_1 = \langle \exp \mathfrak{g}_1 \rangle$ and suppose that for every (minimal) flag manifold $\mathbb{F}_\Theta$ the orbits $G_1 \cdot y$ through the attractor fixed point set $\mathrm{att}_\Theta(H_1)$ are not contractible in $\mathbb{F}_\Theta$. Then a subset $\Gamma \subset G$ generates G as a semigroup if $G_1 \subset \Gamma$ and the subgroup generated by Γ is Zariski dense.*

In the special case when $H_1 \in \mathfrak{a}^+$, that is, $\mathfrak{g}_1$ contains a regular real element of $\mathfrak{g}$, the attractor fixed point $\mathrm{att}_\Theta(H_1)$ reduces to b_Θ. In this case we need to check contractibility only of the orbits $G_1 \cdot b_\Theta$ through the origin. For later reference we record this fact.

Corollary 3.3 *With the notation of Proposition 3.2 suppose that* $H_1 \in \mathfrak{a}^+$*. Then the same result holds with the assumption that* $G_1 \cdot b_\Theta$ *is not contractible in any (minimal) flag manifold.*

4 Split real forms and subgroups $G(\alpha)$

We assume in this section that $\mathfrak{g}$ is a split real form of a complex simple Lie algebra and G is a connected Lie group with Lie algebra G and having finite center. Take a Cartan decomposition $\mathfrak{g} = \mathfrak{k} \oplus \mathfrak{s}$ and a maximal abelian $\mathfrak{a} \subset \mathfrak{s}$. If α is a root of the pair $(\mathfrak{g}, \mathfrak{a})$ then the subalgebra $\mathfrak{g}(\alpha)$ generated by the root spaces $\mathfrak{g}_{\pm\alpha}$ is isomorphic to $\mathfrak{sl}(2, \mathbb{R})$. Precisely, we choose $X_\alpha \in \mathfrak{g}_\alpha$, $X_{-\alpha} = -\theta X_\alpha \in \mathfrak{g}_{-\alpha}$ such that $\langle X_\alpha, X_{-\alpha} \rangle = 1$. Then the isomorphism is given by

$$X_\alpha \leftrightarrow \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \qquad H_\alpha \leftrightarrow \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \qquad X_{-\alpha} \leftrightarrow \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}.$$

In order to apply the ideas of Section 3 we fix a Weyl chamber $\mathfrak{a}^+$ such that $H_\alpha \in \mathrm{cl}\mathfrak{a}^+$. Then α is positive w.r.t. $\mathfrak{a}^+$ and we get compatible Iwasawa decompositions $\mathfrak{g}(\alpha) = \mathfrak{k}_{H_\alpha} \oplus \langle H_\alpha \rangle \oplus \mathfrak{g}_\alpha \subset \mathfrak{g} = \mathfrak{k} \oplus \mathfrak{a} \oplus \mathfrak{n}$ where $\mathfrak{k}_{H_\alpha}$ is spanned by $A_\alpha = X_\alpha - X_{-\alpha}$. We put $G(\alpha) = \langle \exp \mathfrak{g}(\alpha) \rangle$.

Our objective is to check whether the conditions of Proposition 3.2 are satisfied by $G(\alpha)$. The following result reduces the question to the orbit through the origin b_Θ of a flag manifold $\mathbb{F}_\Theta$. (Where the origins are given by the standard parabolic subalgebras defined from the Weyl chamber $\mathfrak{a}^+$.)

Theorem 4.1 *In a flag manifold* $\mathbb{F}_\Theta$ *take* $y \in \mathrm{att}_\Theta(H_\alpha)$*. Then the orbit* $G(\alpha) \cdot y$ *is a circle* S^1 *homotopic to the orbit* $G(\alpha) \cdot b_\Theta$*.*

The proof this theorem requires some lemmas. We start by looking at the orbit $G(\alpha) \cdot b_\Theta$. By compatibility of the Iwasawa decompositions it follows that the parabolic subalgebra $\mathfrak{p}_\alpha = \langle H_\alpha \rangle \oplus \mathfrak{g}_\alpha$ of $\mathfrak{g}(\alpha)$ is contained in the isotropy subalgebra at b_Θ for any flag manifold $\mathbb{F}_\Theta$. To get the inclusion of the parabolic subgroup of $G(\alpha)$ as well we perform a somewhat standard computation on $\mathfrak{sl}(2, \mathbb{R})$ and $\mathfrak{sl}(2, \mathbb{C})$ (cf. [10], Chapter VII.5).

Proposition 4.2 *Let* $G(\alpha) \subset G$ *be the connected subgroup with Lie algebra* $\mathfrak{g}(\alpha) \approx \mathfrak{sl}(2, \mathbb{R})$ *and* M *the centralizer of* $\mathfrak{a}$ *in* K*. Then the center* $Z(G(\alpha))$ *of* $G(\alpha)$ *is contained in* M*.*

Proof. Let $\widetilde{G} = \widetilde{\mathrm{Sl}(2,\mathbb{R})}$ be the universal covering and denote by $\widetilde{\exp} : \mathfrak{sl}(2,\mathbb{R}) \to \widetilde{\mathrm{Sl}(2,\mathbb{R})}$ the exponential map. Take the basis

$$A = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}, \qquad H = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \qquad S = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$$

of $\mathfrak{sl}(2,\mathbb{R})$. The center $Z\left(\widetilde{\mathrm{Sl}(2,\mathbb{R})}\right)$ of $\widetilde{\mathrm{Sl}(2\mathbb{R})}$ is the kernel of its adjoint representation $\widetilde{\mathrm{Ad}}$ which is explicitly given by

$$Z\left(\widetilde{\mathrm{Sl}(2,\mathbb{R})}\right) = \{\widetilde{\exp}(k\pi A) : k \in \mathbb{Z}\} \approx \mathbb{Z},$$

since the center is contained in a one-parameter group $\widetilde{\exp}(tA)$.

Now $\mathfrak{g}(\alpha) \approx \mathfrak{sl}(2,\mathbb{R})$ with the isomorphism given by $H \leftrightarrow H_\alpha^\vee = \frac{2H_\alpha}{\langle\alpha,\alpha\rangle}$, $A \leftrightarrow A_\alpha = X_\alpha - X_{-\alpha}$ and $S \leftrightarrow S_\alpha = X_\alpha + X_{-\alpha}$, where $X_{\pm\alpha} \in \mathfrak{g}_{\pm\alpha}$ and $\langle X_\alpha, X_{-\alpha}\rangle = 1$.

Suppose first that $G = \mathrm{Aut}_0\mathfrak{g}$ is the adjoint group. Then $G(\alpha) = \widetilde{\mathrm{Sl}(2,\mathbb{R})}/D$ with $D \subset Z\left(\widetilde{\mathrm{Sl}(2,\mathbb{R})}\right)$ given by

$$D = \{\widetilde{\exp}(kn_0\pi A) : k \in \mathbb{Z}\} \approx n_0\mathbb{Z}$$

where

$$n_0 = \min\{n > 0 : e^{n\pi\mathrm{ad}(A_\alpha)} = \mathrm{id}\}.$$

It follows that $Z\left(G(\alpha)\right) = Z\left(\widetilde{\mathrm{Sl}(2,\mathbb{R})}\right)/D \approx \mathbb{Z}_{n_0}$ is generated by $e^{\pi\mathrm{ad}(A_\alpha)}$. Complexifying and doing computations in $\mathrm{Sl}(2,\mathbb{C})$, it turns out that $e^{\pi\mathrm{ad}(A_\alpha)} = e^{\pi\mathrm{ad}(iH_\alpha^\vee)}$. This last term belongs to M showing that $Z\left(G(\alpha)\right) \subset M$ when $G = \mathrm{Aut}_0\mathfrak{g}$. For a general G the same result is obtained by taking adjoints. □

The next lemma will ensure that the isotropy subalgebra at b_Θ for the action of $G\left(\alpha\right)$ is exactly $\mathfrak{p}_\alpha = \langle H_\alpha\rangle \oplus \mathfrak{g}_\alpha$.

Lemma 4.3 *If α is a root with $H_\alpha \in \mathrm{cl}\mathfrak{a}^+$, then* $\mathrm{supp}\alpha = \Sigma$.

Proof. See [19, Proposition 3.3]. □

Now we can describe the orbits through the origins of the flag manifolds.

Lemma 4.4 *Let* b_Θ *be the origin of a flag manifold* $\mathbb{F}_\Theta$ *and* β *a positive root. Then* $G(\beta)\cdot b_\Theta$ *is either a circle* S^1 *or it reduces to a point. If* $\beta\notin\langle\Theta\rangle$ *then* $\dim G(\beta)\cdot b_\Theta=1$. *In particular,* $\dim G(\alpha)\cdot b_\Theta=1$ *if* $H_\alpha\in\mathrm{cl}\mathfrak{a}^+$.

Proof. Let $\mathfrak{g}\left(\beta\right)_{b_\Theta}$ and $G\left(\beta\right)_{b_\Theta}$ be the isotropy subalgebra and subgroup, respectively, at b_Θ for the action of $G\left(\beta\right)$. The subalgebra $\mathfrak{g}\left(\beta\right)_{b_\Theta}$ contains the parabolic subalgebra of $\mathfrak{g}\left(\beta\right)$ given by $\mathfrak{p}_\beta=\mathrm{span}\{H_\beta\}\oplus\mathfrak{g}_\beta\subset\mathfrak{p}_\Theta$. This implies that $G\left(\beta\right)_{b_\Theta}$ contains the identity component $\left(P_\beta\right)_0$ of the parabolic subgroup $P_\beta=\mathrm{Norm}_{G(\beta)}\mathfrak{p}_\beta\subset G\left(\beta\right)$. If $\mathfrak{g}\left(\beta\right)_{b_\Theta}=\mathfrak{p}_\beta$ then $G\left(\beta\right)_{b_\Theta}$ is a union of connected components of P_β. But $P_\beta=Z\left(G(\alpha)\right)\left(P_\beta\right)_0$ and $Z\left(G(\alpha)\right)\subset M\subset P_\Theta$ by Proposition 4.2. Hence, in this case $G\left(\beta\right)_{b_\Theta}=P_\beta$ and the orbit $G\left(\beta\right)\cdot b_\Theta=G\left(\beta\right)/P_\beta\approx S^1$. On the other hand if $\mathfrak{p}_\beta\neq\mathfrak{g}\left(\beta\right)_{b_\Theta}$ then $\mathfrak{g}\left(\beta\right)_{b_\Theta}=\mathfrak{g}\left(\beta\right)$, so that $G\left(\beta\right)_{b_\Theta}=G\left(\beta\right)$ and the orbit $G\left(\beta\right)\cdot b_\Theta$ reduces to a point.

Now, if $\beta\notin\langle\Theta\rangle$ then $\mathfrak{g}_{-\beta}$ has empty intersection with the isotropy subalgebra $\mathfrak{p}_\Theta$ which implies that $\mathfrak{g}\left(\beta\right)_{b_\Theta}=\mathfrak{p}_\beta$. Hence $G\left(\beta\right)\cdot b_\Theta$ is a circle S^1 if $\beta\notin\langle\Theta\rangle$. The last statement is a consequence of Lemma 4.3. □

We proceed now to look at the orbits of $G(\alpha)$ through $y\in\mathrm{att}_\Theta(H_\alpha)$. We recall that $\mathrm{att}_\Theta(H_\alpha)=\left(K_{H_\alpha}\right)_0\cdot b_\Theta$, where $\left(K_{H_\alpha}\right)_0$ is the identity component of the compact part of the centralizer Z_{H_α} of H_α. The Lie algebra $\mathfrak{k}_{H_\alpha}$ of K_{H_α} is spanned by $A_\alpha=X_\alpha-X_{-\alpha}$.

Let $y=u\cdot b_\Theta\in\mathrm{att}_\Theta(H_\alpha)$ with $u\in\left(K_{H_\alpha}\right)_0$. Then

$$G(\alpha)\cdot y=u\left(u^{-1}G(\alpha)u\right)\cdot b_\Theta.$$

The group $u^{-1}G(\alpha)u$ is isomorphic to $G(\alpha)$ and its Lie algebra $\mathrm{Ad}(u^{-1})\mathfrak{g}(\alpha)$ is isomorphic to $\mathfrak{g}(\alpha)$ and hence to $\mathfrak{sl}(2,\mathbb{R})$. Since $\mathrm{Ad}\left(u\right)H_\alpha=H_\alpha$, the decomposition of $\mathrm{Ad}(u^{-1})\mathfrak{g}(\alpha)$ into root spaces is given by

$$\mathrm{Ad}\left(u^{-1}\right)\mathfrak{g}(\alpha)=\langle H_\alpha\rangle\oplus\mathrm{Ad}\left(u^{-1}\right)\mathfrak{g}_\alpha\oplus\mathrm{Ad}\left(u^{-1}\right)\mathfrak{g}_{-\alpha}.$$

The subspace $\mathfrak{p}_u=\langle H_\alpha\rangle\oplus\mathrm{Ad}(u^{-1})\mathfrak{g}_\alpha$ is a parabolic subalgebra of $\mathrm{Ad}(u^{-1})\mathfrak{g}(\alpha)$. Denote by P_u the corresponding parabolic subgroup.

Lemma 4.5 *The subgroup* P_u *is contained in the isotropy subgroup at* b_Θ *of the action of* $u^{-1}G(\alpha)u$.

Proof. We have that $\langle H_\alpha \rangle$ is contained in the isotropy algebra, because b_Θ is a fixed point of e^{tH_α}. To see that the same occurs with $\mathrm{Ad}(u^{-1})(\mathfrak{g}_\alpha)$, note that if $0 \neq X \in \mathrm{Ad}(u^{-1})(\mathfrak{g}_\alpha)$ then $\mathrm{ad}(H_\alpha)(X) = \alpha(H_\alpha)X$ because u centralizes H_α. Hence X is an eigenvector of $\mathrm{ad}(H_\alpha)$ associated to the eigenvalue $\alpha(H_\alpha) = \langle \alpha, \alpha \rangle > 0$. Since $H_\alpha \in \mathrm{cl}\mathfrak{a}^+$ we have that the eigenspaces of $\mathrm{ad}(H_\alpha)$ associated to positive eigenvalues are contained in $\mathfrak{n}^+$. Therefore $X \in \mathfrak{n}^+$ so that $\mathrm{Ad}(u^{-1})(\mathfrak{g}_\alpha) \subset \mathfrak{n}^+$, implying that $\mathrm{Ad}(u^{-1})(\mathfrak{g}_\alpha)$ is contained in the isotropy subalgebra at b_Θ.

Now, the proof follows as in Lemma 4.4 by checking that any connected component of P_u is contained in the isotropy subgroup at b_Θ. $\square$

As a complement to this lemma we have the following homotopy property. From it the proof of Theorem 4.1 follows quickly.

Lemma 4.6 *The orbit $(u^{-1}G(\alpha)u) \cdot b_\Theta$ is a circle S^1 homotopic to the orbit $G(\alpha) \cdot b_\Theta$, by a homotopy that fixes b_Θ.*

Proof. Let $u_t \in (K_{H_\alpha})_0$, $t \in [0,1]$, be a continuous curve with $u_0 = 1$ e $u_1 = u$. Define the continuous map $\psi : [0,1] \times G(\alpha) \to \mathbb{F}_\Theta$ by

$$\psi(t,g) = u_t^{-1} g u_t \cdot b_\Theta.$$

This map has the factorization

$$\begin{tikzcd}
{[0,1] \times G(\alpha)} \arrow[r] \arrow[d] & \mathbb{F}_\Theta \\
{[0,1] \times (G(\alpha)/P_\alpha)} \arrow[ur] &
\end{tikzcd}$$

that defines a continuous map $\phi : [0,1] \times (G(\alpha)/P_\alpha) \to \mathbb{F}_\Theta$ by $\phi(t, gP_\alpha) = \psi(t,g)$. Indeed, ϕ is well defined because if $h \in P_\alpha$ then $u_t^{-1} h u_t \in P_{u_t}$ and, by the previous lemma, $(u_t^{-1} h u_t) \cdot b_\Theta = b_\Theta$. Hence

$$\psi(gh) = u_t^{-1} g u_t (u_t^{-1} h u_t) \cdot b_\Theta = u_t^{-1} g u_t \cdot b_\Theta = \phi(g)$$

and so ϕ is well defined. The function ϕ is continuous and if b_α denotes the origin of $G(\alpha)/P_\alpha$ then, again by the previous lemma, we have that $\phi(t, b_\alpha) = b_\Theta$ for all $t \in [0,1]$.

Therefore, looking at $G(\alpha)/P_\alpha$ as a circle S^1 with distinguished point $b_\alpha = 1 \cdot P_\alpha$ we see that ϕ is a homotopy between $\phi(0, \cdot)$ whose image is

$G(\alpha)\cdot b_\Theta$ and $\phi(1,\cdot)$ whose image is $(u^{-1}G(\alpha)u)\cdot b_\Theta$. This homotopy fixes b_Θ. $\square$

Now we can finish the proof of Theorem 4.1: Let $u \in (K_{H_\alpha})_0$ be such that $y = ub_\Theta$. Then $G(\alpha)\cdot y = u\,(u^{-1}G(\alpha)u)\cdot b_\Theta$, so that $G(\alpha)\cdot y$ and $(u^{-1}G(\alpha)u)\cdot b_\Theta$ are homotopic by a homotopy defined by a curve $t\in[0,1]\mapsto u_t \in (K_{H_\alpha})_0$ with $u_0 = 1$ and $u_1 = u$. By the previous lemma it follows that $G(\alpha)\cdot y$ and $G(\alpha)\cdot b_\Theta$ are homotopic.

Combining Theorem 4.1 with Proposition 3.2 we arrive at once at the following result.

Theorem 4.7 *Let α be a root and $\mathfrak{a}^+$ a Weyl chamber with $H_\alpha \in \mathrm{cl}\mathfrak{a}^+$. Define the standard parabolic subgroups P_Θ with respect the positive roots associated to $\mathfrak{a}^+$ and denote by b_Θ the origin of $\mathbb{F}_\Theta = G/P_\Theta$. Take a subset $\Gamma \subset G$ with $G(\alpha)\subset\Gamma$. Assume that*

1. *for every minimal flag manifold $\mathbb{F}_\Theta$ the orbit $G(\alpha)\cdot b_\Theta$ (which is a closed curve) is not homotopic to a point and*
2. *the subgroup generated by Γ is Zariski dense.*

Then Γ generates G as semigroup.

As will be seen below condition (1) of this theorem holds in three cases namely when $\mathfrak{g} = \mathfrak{sl}(n,\mathbb{R})$, α is a long root of $\mathfrak{sp}(n,\mathbb{R})$ and α is a short root of the G_2 digram.

4.1 The fundamental group of minimal flag manifolds

We look here at the fundamental groups of the minimal flag manifolds and the homotopy classes of the orbits $G(\alpha)\cdot b_\Theta$ appearing in Theorem 4.7.

Fix a simple system of roots Σ. For a root α we choose $X_\alpha \in \mathfrak{g}_\alpha$, $X_{-\alpha} = -\theta X_\alpha \in \mathfrak{g}_{-\alpha}$ such that $\langle X_\alpha, X_{-\alpha}\rangle = 1$, and write $A_\alpha = X_\alpha - X_{-\alpha} \in \mathfrak{k}_\alpha$ and $S_\alpha = X_\alpha + X_{-\alpha}$. If $\mathbb{F}_\Theta$, $\Theta\subset\Sigma$, is a flag manifold we write b_Θ for its origin defined by Σ. Then for a root α the orbit $G(\alpha)\cdot b_\Theta$ is the closed curve $e^{tA_\alpha}\cdot b_\Theta$. We denote by c_α^Θ (or simply c_α) the homotopy class of this curve in the fundamental group of $\mathbb{F}_\Theta$.

The fundamental groups of real flag manifolds were described in Wiggerman [21] by generators and relations. We recall the result of [21] the case of a split real form $\mathfrak{g}$.

Theorem 4.8 *The fundamental group* $\pi_1(\mathbb{F}_\Theta)$ *of* $\mathbb{F}_\Theta$ *is generated by* c_α *with* $\alpha \in \Sigma$, *subjected to the relations*

1. $c_\alpha = 1$ *if* $\alpha \in \Theta$ *and*
2. $c_\alpha c_\beta c_\alpha^{-1} c_\beta^{-\varepsilon(\alpha,\beta)} = 1$ *where* $\varepsilon(\alpha,\beta) = (-1)^{\langle \alpha^\vee, \beta \rangle}$ *and* $\langle \alpha^\vee, \beta \rangle = \frac{2\langle \alpha^\vee, \beta \rangle}{\langle \alpha, \alpha \rangle}$ *is the Killing number.*

The first relation says that $\pi_1(\mathbb{F}_\Theta)$ is in fact generated by c_α with $\alpha \in \Sigma \setminus \Theta$. However it is convenient to include in the statement the generators c_α, $\alpha \in \Theta$, because they enter in the second set of relations. Namely, $c_\beta c_\beta^{-\varepsilon(\alpha,\beta)} = c_\alpha c_\beta c_\alpha^{-1} c_\beta^{-\varepsilon(\alpha,\beta)} = 1$ if $\alpha \in \Theta$ and $\beta \in \Sigma \setminus \Theta$. Notice that this relation implies that $c_\beta^2 = 1$, $\beta \in \Sigma \setminus \Theta$, if there exists a root $\alpha \in \Theta$ such that the Killing number $\langle \alpha^\vee, \beta \rangle$ is odd.

From these generators and relations it is easy to get the fundamental groups of the minimal flag manifolds. Given a root $\beta \in \Sigma$ we write $\Theta_\beta = \Sigma \setminus \{\beta\}$ and take the corresponding minimal flag manifold $\mathbb{F}_{\Theta_\beta}$. These exaust the minimal flag manifolds, except for the diagram A_1 when the only flag manifold is given by $\Theta = \emptyset$.

Proposition 4.9 *The fundamental group of a minimal flag manifold* $\mathbb{F}_{\Theta_\beta}$ *is* $\pi_1(\mathbb{F}_{\Theta_\beta}) = \mathbb{Z}_2$ *except in for* A_1 *or when* β *is the long root in the* C_l *diagram. In the exceptions* $\pi_1(\mathbb{F}_{\Theta_\beta}) = \mathbb{Z}$.

Proof. By Theorem 4.8 the fundamental group of $\mathbb{F}_{\Theta_\beta}$ is cyclic and generated by c_β. If the diagram is not A_1 then β is linked to another root α. If the link is a simple edge then $\langle \alpha^\vee, \beta \rangle = -1$ and hence $c_\beta^2 = 1$ so that $\pi_1(\mathbb{F}_{\Theta_\beta}) = \mathbb{Z}_2$. The Killing number $\langle \alpha^\vee, \beta \rangle$ is also odd in the G_2 diagram (-1 or -3) or in case α is a long root and β a short root. A glance at the Dynkin diagrams shows that every root β has such link if β is not the long root in the C_l diagram. If β is this long root then there are no relations involving c_β and hence $\pi_1(\mathbb{F}_{\Theta_\beta})$ is cyclic infinity.

Finally, the flag manifold of A_1 is the circle S^1 and hence has $\mathbb{Z}$ as fundamental group. □

We proceed now to look at the homotopy condition of Theorems 4.1 and 4.7. Here we change slightly the point of view. In those theorems we started with a root α and choosed a Weyl chamber containing H_α in its closure.

Here we fix a Weyl chamber $\mathfrak{a}^+$ (and hence an origin b_Θ in a flag manifold $\mathbb{F}_\Theta$) and take a root μ such that $H_\mu \in \mathrm{cl}\mathfrak{a}^+$. Since the Weyl group $\mathcal{W}$ acts transitively on the set of Weyl chambers, there is no loss of generality in fixing $\mathfrak{a}^+$ in advance. In fact, by $wH_\alpha = H_{w\alpha}$ it follows that for any root α there exists a root $\mu = w\alpha$ such that $H_\mu \in \mathrm{cl}\mathfrak{a}^+$, that is, $H_\alpha \in \mathrm{cl}\left(w^{-1}\mathfrak{a}^+\right)$. If $\overline{w} \in M^*$ is a representative of w then $G(\alpha) = \overline{w}^{-1}G(\mu)\,\overline{w}$ and $G(\alpha)\cdot\overline{w}^{-1}b_\Theta = \overline{w}^{-1}G(\mu)\,\overline{w}\cdot\overline{w}^{-1}b_\Theta = \overline{w}^{-1}\left(G(\mu)\cdot b_\Theta\right)$. The point $\overline{w}^{-1}b_\Theta$ is the origin corresponding to $w^{-1}\mathfrak{a}^+$ and a curve $t \in [0,1] \mapsto g_t \in G$ with $g_0 = 1$ and $g_1 = \overline{w}$ realizes a homotopy between the two orbits $G(\alpha)\cdot\overline{w}^{-1}b_\Theta$ and $G(\mu)\cdot b_\Theta$. Therefore we can restrict our analysis to roots μ with $H_\mu \in \mathrm{cl}\mathfrak{a}^+$ and the Weyl chamber $\mathfrak{a}^+$ previously fixed.

The action of $\mathcal{W}$ on the set of roots is either transitive (for the simply laced diagrams A_l, D_l, E_6, E_7 and E_8) or has two orbits the long and short roots (for the other diagrams B_l, C_l, F_4 and G_2). This implies that for the simply laced diagrams there is just one root (the highest positive root) μ with $H_\mu \in \mathrm{cl}\mathfrak{a}^+$ while in the other cases there is the highest root and a short root as well in the closure of the Weyl chamber.

To look at the classes c_μ^Θ with $H_\mu \in \mathrm{cl}\mathfrak{a}^+$ in the fundamental groups of the minimal flag manifolds we realize them as orbits of projective representations.

4.2 Projective and spherical orbits

To look at the fundamental group of the flag manifolds we shall exploit their realizations as projective orbits of representations. Given the simple system of roots $\Sigma = \{\alpha_1, \ldots, \alpha_l\}$ let $\{\omega_1, \ldots, \omega_l\}$ be the set of basic weights defined by

$$\langle \alpha_i^\vee, \omega_j \rangle = \frac{2\langle \alpha_i, \omega_j \rangle}{\langle \alpha_i, \alpha_j \rangle} = \delta_{ij}.$$

Any $\omega = p_1\omega_1 + \cdots + p_l\omega_l$, $p_i \in \mathbb{Z}$, $p_i \geq 0$, is the highest weight of a representation ρ_ω of $\mathfrak{g}$ in a vector space V_ω. Write $G = \langle \exp \rho_\omega(\mathfrak{g}) \rangle$ for the group with Lie algebra $\mathfrak{g}$ that integrates the representation.

Let $V(\omega) \subset V_\omega$ be the one-dimensional weight space of ω. For $v \in V(\omega)$, $v \neq 0$, put $V^+(\omega) = \mathbb{R}^+ v$ for the ray spanned by v.

Consider the projective orbit $G \cdot V(\omega) = \{g \cdot V(\omega) : g \in G\}$ and the spherical orbit $G \cdot V^+(\omega) = \{g \cdot V^+(\omega) : g \in G\}$. The isotropy subalgebra at both $V(\omega)$ and $V^+(\omega)$ is the parabolic subalgebra $\mathfrak{p}_{\Theta_\omega}$ where

$$\Theta_\omega = \{\alpha_i \in \Sigma : p_i = 0\} = \{\alpha \in \Sigma : \alpha(\omega) = 0\}.$$

Hence the identity component of the parabolic subgroup P_{Θ_ω} is contained in the isotropy subgroups of $V(\omega)$ and $V^{+}(\omega)$. It turns out that the isotropy subgroup at $V(\omega)$ is the whole P_{Θ_ω}, since $m \cdot v = \pm v$ if $m \in M$. Therefore $G \cdot V(\omega) \approx \mathbb{F}_{\Theta_\omega}$ with the origin $b_{\Theta_\omega} \in \mathbb{F}_{\Theta_\omega}$ being identified to $V(\omega) \in G \cdot V(\omega)$. Also the the map $G \cdot V^{+}(\omega) \to G \cdot V(\omega)$, $g \cdot V^{+}(\omega) \mapsto g \cdot V(\omega)$ is a covering because the isotropy subgroup at $V^{+}(\omega)$ is an open subgroup of P_{Θ_ω}. This covering has one or two leaves, depending if $-V^{+}(\omega)$ belongs or not to the orbit $G \cdot V^{+}(\omega)$.

To look closely at the covering $G \cdot V^{+}(\omega) \to G \cdot V(\omega)$ we take a root α. The orbit $G(\alpha) \cdot b_\Theta$ is the curve $(\exp tA_\alpha) \cdot b_\Theta$, $t \in [0, \pi]$, where $A_\alpha = X_\alpha - X_{-\alpha}$. This means that $m_\alpha v = \pm v$ if $v \in V(\omega)$, where $m_\alpha = \exp \pi \rho_\omega(A_\alpha)$. The following lemma gives the sign in this equality.

Lemma 4.10 $m_\alpha v = (-1)^{\omega(H_\alpha^\vee)} v$.

Proof. The Lie algebra $\rho_\omega(\mathfrak{g})$ as well as the Lie group $G = \langle \exp \rho_\omega(\mathfrak{g}) \rangle$ can be complexified. In the complexification we have $m_\alpha = \exp \pi \rho_\omega(A_\alpha) = \exp i\pi \rho_\omega(H_\alpha^\vee)$ (cf. Proposition 4.2). Hence $m_\alpha v = e^{i\pi\omega(H_\alpha^\vee)} v = (-1)^{\omega(H_\alpha^\vee)} v$ if $v \in V(\omega)$. $\square$

Now let $\omega = \omega_j$ be a basic weight, so that $\Theta_{\omega_j} = \Sigma \setminus \{\alpha_j\}$, and $\mathbb{F}_{\Theta_{\omega_j}}$ is a minimal flag manifold. By the very definition of the basic weights we have $\omega_j \left(H_{\alpha_j}^\vee \right) = 1$, so that $m_{\alpha_j} v = -v$ if $v \in V(\omega_j)$. This implies that the spherical orbit $G \cdot V^{+}(\omega_j)$ is a double covering of $\mathbb{F}_{\Theta_{\omega_j}}$.

On the other hand we have, by Proposition 4.9, that except in two cases the fundamental group of a minimal flag manifold is $\mathbb{Z}_2$. Combining these facts we get the universal covering space of the minimal flag manifolds.

Proposition 4.11 *Let ω_j be a basic weight in a diagram different from A_1 and such that α_j is not the long root of the C_l diagram. Let $\mathbb{F}_{\Theta_{\omega_j}}$ be the corresponding minimal flag manifold. Then the spherical orbit $G \cdot V^{+}(\omega_j)$ is the simply connected universal cover of $\mathbb{F}_{\Theta_{\omega_j}}$.*

Proof. In fact, $\mathbb{F}_{\Theta_{\omega_j}}$ has only two coverings since its fundamental group is $\mathbb{Z}_2$. Since $G \cdot V^{+}(\omega_j) \to \mathbb{F}_{\Theta_{\omega_j}}$ is a double covering it follows that $G \cdot V^{+}(\omega_j)$ is indeed the simply connected cover. $\square$

As a consequence we have that a closed curve in $\mathbb{F}_{\Theta_{\omega_j}}$ is null homotopic if and only if its lifting to $G \cdot V^+(\omega_j)$ is a closed curve. This yields the following criterion to decide if an orbit $G(\alpha) \cdot b_\Theta$ is null homotopic.

Proposition 4.12 *Let $\mathbb{F}_{\Theta_{\omega_j}}$ be a minimal flag manifold with ω_j as in Proposition 4.11. If α is a root then $G(\alpha) \cdot b_{\Theta_{\omega_j}}$ is null homotopic if and only if the Killing number $\omega_j(H_\alpha^\vee)$ is even.*

Proof. The orbit $G(\alpha) \cdot b_{\Theta_{\omega_j}}$ is the closed curve $(\exp tA_\alpha) \cdot b_{\Theta_{\omega_j}}$, $t \in [0, \pi]$. In terms of the projective orbit of the representation this curve is given by $\exp t\rho_{\omega_j}(A_\alpha) \cdot V(\omega_j)$, $t \in [0, \pi]$. The lifting of this curve to $G \cdot V^+(\omega_j)$ starting at $V^+(\omega_j)$ is $\exp t\rho_{\omega_j}(A_\alpha) \cdot V^+(\omega_j)$, $t \in [0, \pi]$. This lifting is a closed curve if and only if $m_\alpha \cdot v = \exp \pi\rho_{\omega_j}(A_\alpha) \cdot v = v$ for $v \in V(\omega_j)$. By Lemma 4.10 we have $m_\alpha v = (-1)^{\omega_j(H_\alpha^\vee)} v$, so that $G(\alpha) \cdot b_{\Theta_{\omega_j}}$ is null homotopic if and only if $\omega_j(H_\alpha^\vee)$ is even. $\square$

If $\alpha = n_1\alpha_1 + \cdots + n_l\alpha_l$ where $\Sigma = \{\alpha_1, \ldots, \alpha_l\}$ is the simple system of roots then we can compute $\omega_j(H_\alpha^\vee)$ explicitly from the coefficients n_j. In fact, since $\langle \alpha_i, \omega_j \rangle = 0$ if $i \neq j$ and $2\langle \alpha_j, \omega_j \rangle = \langle \alpha_j, \alpha_j \rangle$, we get

$$\omega_j(H_\alpha^\vee) = \frac{2\langle \alpha, \omega_j \rangle}{\langle \alpha, \alpha \rangle} = n_j \frac{2\langle \alpha_j, \omega_j \rangle}{\langle \alpha, \alpha \rangle} = n_j \frac{\langle \alpha_j, \alpha_j \rangle}{\langle \alpha, \alpha \rangle}. \tag{1}$$

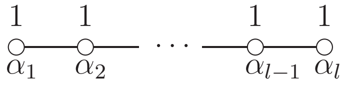
By this formula we see that $G(\alpha) \cdot b_{\Theta_{\omega_j}}$ is null homotopic if n_j is even and the roots have the same length. We observe the following possibilities when the roots α_j and α have different length.

1. α_j is long and α is short with $\langle \alpha_j, \alpha_j \rangle = 2\langle \alpha, \alpha \rangle$. Then $G(\alpha) \cdot b_{\Theta_{\omega_j}}$ is null homotopic regardless the coefficient n_j.
2. α is long and α_j is short with $\langle \alpha, \alpha \rangle = 2\langle \alpha_j, \alpha_j \rangle$. Then $G(\alpha) \cdot b_{\Theta_{\omega_j}}$ is not null homotopic if $n_j \neq 4p$.

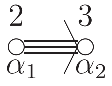
4.3 Roots in the closure of the Weyl chamber

Now we can look at the homotopy class of the orbits $G(\alpha) \cdot b_\Theta$ in a minimal flag manifold, for a root α with $H_\alpha \in \mathrm{cl}\mathfrak{a}^+$. Concerning the highest roots we write their coefficients above the simple roots in the Dynkin diagrams:

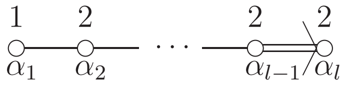
$A_l, l \geq 1$



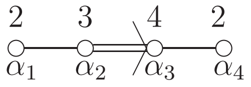
G_2



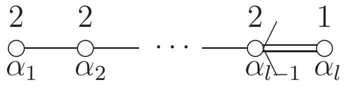
$B_l, l \geq 2$



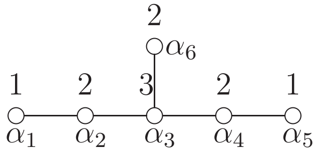
F_4



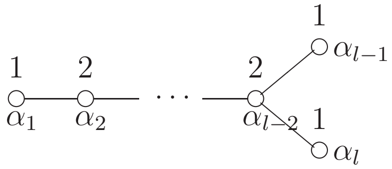
$C_l, l \geq 3$



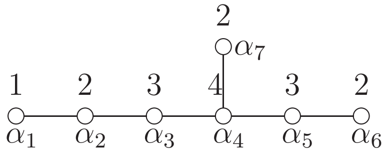
E_6



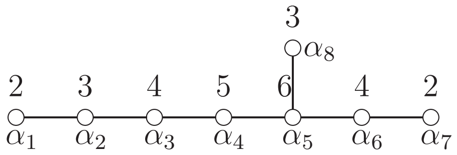
$D_l, l \geq 4$



E_7



E_8



Consider first the highest root μ. By inspecting the coefficients of μ we can apply formula (1) to get the following to cases where $G(\mu) \cdot b_\Theta$ is not null homotopic in whatsoever minimal flag manifold:

1. A_l, because the coefficients are $n_j = 1$ and the roots have the same length.
2. C_l, in this case the highest root μ has coefficients $n_j = 2$ only with respect to the short roots α_j, $j < l$. So that $\omega_j\left(H_\mu^\vee\right) = 1$ for every j.

In the diagrams D_l, E_6, E_7 and E_8, the roots have the same length and the coefficients n_j are even for several j. This means that for these diagrams $G(\mu) \cdot b_\Theta$ is null homotopic on several minimal flag manifolds. We have also that in the diagrams B_l, G_2 and F_4, the Killing number $\omega_j\left(H_\mu^\vee\right)$ is even if α_j is a short simple root for several j. Hence for these diagrams $G(\mu) \cdot b_\Theta$ is null homotopic on several minimal flag manifolds.

Now let $\overline{\mu}$ be the short root with $H_{\overline{\mu}} \in \mathrm{cl}\mathfrak{a}^+$ in the diagrams with multiple edges. For B_l, C_l and F_4, the Killing number $\omega_j\left(H_{\overline{\mu}}^{\vee}\right)$ is even if α_j is a long simple root. Hence for these diagrams $G\left(\overline{\mu}\right) \cdot b_\Theta$ is null homotopic on several minimal flag manifolds.

On the other hand, in G_2 we have $\overline{\mu} = \alpha_1 + 3\alpha_2$. Hence by formula (1), $\omega_j\left(H_{\overline{\mu}}^{\vee}\right)$ is odd for $j = 1, 2$. This means that for G_2 the orbits $G\left(\overline{\mu}\right) \cdot b_\Theta$ in the minimal flag manifolds are not null homotopic.

Having these facts about the fundamental groups Theorem 4.7 yields immediately following result.

Theorem 4.13 *Let $\Gamma \subset G$ be a subset such that $G\left(\alpha\right) \subset \Gamma$ and the group generated by Γ is Zariski dense. Then Γ generates G in the following cases:*

1. $\mathfrak{g} = \mathfrak{sl}\left(l+1, \mathbb{R}\right)$.
2. $\mathfrak{g} = \mathfrak{sp}\left(l, \mathbb{R}\right)$ *and α is a long root.*
3. $\mathfrak{g}$ *is the split real form associated to G_2 and α is a short root.*

4.4 Example: Short roots in $\mathfrak{sp}\left(n, \mathbb{R}\right)$

We present an example showing that the result of Theorem 4.13 does not hold if α is a short root of the symplectic Lie algebra $\mathfrak{sp}\left(l, \mathbb{R}\right)$. Let Q be the quadratic form in $\mathbb{R}^{2l}$ whose matrix with respect to the standard basis $\{e_1, \ldots, e_l, f_1, \ldots, f_l\}$ is

$$[Q] = \begin{pmatrix} 0 & \mathrm{id}_{l\times l} \\ \mathrm{id}_{l\times l} & 0 \end{pmatrix}.$$

Define the subset of the projective space $C \subset \mathbb{P}^{2l-1}$ by

$$C = \{[v] \in \mathbb{P}^{2l-1} : Q\left(v\right) \geq 0\}$$

where $[v] = \mathrm{span}\{v\}$, $0 \neq v \in \mathbb{R}^{2l}$. It is easily seen that C is compact and has interior $\mathrm{int}C = \{[v] \in \mathbb{P}^{2l-1} : Q\left(v\right) > 0\}$.

Now define $S \subset \mathrm{Sp}(l, \mathbb{R})$ to be the compression semigroup

$$S = \{g \in \mathrm{Sp}\left(l, \mathbb{R}\right) : gC \subset C\}.$$

We claim that $\mathrm{int} S \neq \emptyset$. In fact, $X = [Q]$ is itself a symplectic matrix and for any $0 \neq v \in \mathbb{R}^{2l}$ we have

$$\frac{d}{dt} Q\left(e^{tX} v\right) = \left(e^{tX} v\right)^T \left(X^T [Q] + [Q] X\right) e^{tX} v = 2\left(e^{tX} v\right)^T e^{tX} v > 0,$$

so that $t \mapsto Q\left(e^{tX} v\right)$ is strictly increasing. This implies that for $t > 0$, $e^{tX} C \subset \mathrm{int} C \subset C$ hence $e^{tX} \in S$ if $t \geq 0$. Actually, $e^{tX} \in \mathrm{int} S$ if $t > 0$ by continuity with respect to the compact-open topology.

Now, take a symplectic matrix of the form

$$Y = \begin{pmatrix} A & 0 \\ 0 & -A^T \end{pmatrix}.$$

Then $Y^T [Q] + [Q] Y = 0$, so that e^{tY}, $t \in \mathbb{R}$, is an isometry of Q, that is, $Q\left(e^{tY} v\right) = Q(v)$ for $v \in \mathbb{R}^{2l-1}$. Hence $e^{tY} \in S$, $t \in \mathbb{R}$, which in turn implies that the group

$$G = \{ \begin{pmatrix} g & 0 \\ 0 & \left(g^{-1}\right)^T \end{pmatrix} \in \mathrm{Sp}(l, \mathbb{R}) : g \in \mathrm{Gl}^+(l, \mathbb{R}) \}$$

is contained in S. But for any short root $\alpha = \lambda_i - \lambda_j$, $i \neq j$, we have $G(\alpha) \subset G$, concluding our example.

5 Representations of $\mathfrak{sl}(2, \mathbb{C})$

In this section we take an irreducible representation of $\mathfrak{sl}(2, \mathbb{C})$ on $\mathbb{C}^{n+1}$, that is, a homomorphism $\rho_n : \mathfrak{sl}(2, \mathbb{C}) \to \mathfrak{sl}(n+1, \mathbb{C})$ and look at the subgroup $G_1 = \langle \exp \rho_n (\mathfrak{sl}(2, \mathbb{C})) \rangle \subset \mathrm{Sl}(n+1, \mathbb{C})$. As an application of the previous results will show the following result.

Theorem 5.1 *Let $\rho_n : \mathfrak{sl}(2, \mathbb{C}) \to \mathfrak{sl}(n+1, \mathbb{C})$ be the irreducible $(n+1)$-dimensional representation of $\mathfrak{sl}(2, \mathbb{C})$ and suppose that $\Gamma \subset \mathrm{Sl}(n+1, \mathbb{C})$ is a subset containing $G_1 = \langle \exp \rho_n (\mathfrak{sl}(2, \mathbb{C})) \rangle$ such that the group generated by Γ is Zariski dense. Then Γ generates $\mathrm{Sl}(n+1, \mathbb{C})$ as a semigroup.*

Given the basis

$$X = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \qquad H = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \qquad Y = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$$

of $\mathfrak{sl}(2,\mathbb{C})$ we choose a basis $\{v_0, v_1, \ldots, v_n\}$ of $\mathbb{C}^{n+1}$ such that

$$\rho_n(H) = \mathrm{diag}\{n, n-2, \ldots, -n+2, -n\},$$

$\rho_n(Y)v_j = v_{j+1}$ and $\rho_n(X)v_j = j(n-j+1)v_{j-1}$. The diagonal matrix $\rho_n(H)$ is a regular real element of $\mathrm{Sl}(n+1,\mathbb{C})$ and is contained in the standard Weyl chamber $\mathfrak{a}^+$ formed by real diagonal matrices with strict decreasing eigenvalues. Hence $G_1 = \langle \exp \rho_n(\mathfrak{sl}(2,\mathbb{C}))\rangle$ is in the case covered by Corollary 3.3. To apply it we must look at the homotopy properties of the orbits $G_1 \cdot b_\Theta$ on the minimal flag manifolds of $\mathrm{Sl}(n+1,\mathbb{C})$, that is on the Grassmannians $\mathrm{Gr}_k(n+1)$ of k-dimensional subspaces of $\mathbb{C}^{n+1}$.

By the choice of the standard Weyl chamber $\mathfrak{a}^+$ the origin of $\mathrm{Gr}_k(n+1)$ is the subspace b_k spanned by $\{v_0, v_1, \ldots, v_{k-1}\}$. An easy computation shows that the parabolic subalgebra $\mathfrak{p} = \mathrm{span}_{\mathbb{C}}\{\rho_n(H), \rho_n(X)\}$ is contained in the isotropy subalgebra at any b_k. Since the corresponding parabolic subgroup $P \subset G_1$ is connected (G_1 is a complex Lie group) it follows that the isotropy subgroups at b_k contain P. On the other Y does not belong to the isotropy subalgebras of b_k. This implies that the isotropy subgroup at b_k of the action of G_1 is the parabolic subgroup P. Hence all the orbits $G_1 \cdot b_k$ are $G_1/P \approx S^2$.

In the sequel it will be proved that the orbits $G_1 \cdot b_k$ are not contractible in $\mathrm{Gr}_k(n+1)$. This will be done by showing that a canonical line bundle over $\mathrm{Gr}_k(n+1)$ is not trivial when restricted (pull backed) to $S^2 \approx G_1/P$. This approach is based on the following proposition about the restriction of the tautological line bundle $\mathbb{C}^n \setminus \{0\} \to \mathbb{P}^n$ to the projective orbit $S^2 \approx \langle \exp \rho_n(\mathfrak{sl}(2,\mathbb{C}))\rangle [v_0]$ in the irreducible representation.

Proposition 5.2 *Let $\rho_n : \mathfrak{sl}(2,\mathbb{C}) \to \mathfrak{sl}(n+1,\mathbb{C})$ be the irreducible representation of $\mathfrak{sl}(2,\mathbb{C})$ on $\mathbb{C}^{n+1}$, $n \geq 1$. With the notation as above let $G_1 \cdot [v_0] \subset \mathbb{P}^n$ be the projective orbit of the highest weight space $[v_0]$. Then $G_1 \cdot [v_0]$ is diffeomorphic to S^2.*

Let $\pi : \mathbb{C}^{n+1} \setminus \{0\} \to \mathbb{P}^n$ the tautological line bundle over $\mathbb{P}^n$ and denote by τ_n its restriction (pull back) to $S^2 = G_1 \cdot [v_0]$. Then τ_n is not a trivial line bundle. In fact τ_n is represented by the homotopy class $n \in \mathbb{Z} = \pi_1(\mathbb{C}_\times)$.

Proof. For the proof we view τ_n as a bundle $\xi_1 \cup_a \xi_2$ obtained by clutching along the equator S^1 trivial bundles ξ_1 and ξ_2 on the north and south hemispheres. Such a bundle is trivial if and only if the clutching function $a : S^1 \to \mathbb{C}_\times$ is homotopic to a point (see Husemoller [7], Chapter 9.7).

The set $\sigma = \{[e^{z\rho_n(Y)}v_0] \in S^2 : z \in \mathbb{C}\}$ is an open Bruhat cell in the flag manifold $S^2 = G_1 \cdot [v_0]$ of $\mathfrak{sl}\,(2, \mathbb{C})$ since $\mathfrak{n}^- = \operatorname{span}_{\mathbb{C}}\{Y\}$ is the nilpotent component of an Iwasawa decomposition. Hence σ is open and dense. Actually, $\sigma = S^2 \setminus \{[v_n]\}$ because $[v_n]$ is the space of lowest weight. Furthermore the map

$$\phi : z \in \mathbb{C} \longmapsto [e^{z\rho_n(Y)}v_0] \in S^2 \setminus \{[v_n]\}$$

is a chart. This map yields the following section over $S^2 \setminus \{[v_n]\}$ of the tautological bundle:

$$\chi_1 : [e^{z\rho_n(Y)}v_0] \in S^2 \setminus \{[v_n]\} \longmapsto e^{z\rho_n(Y)}v_0.$$

The same way

$$\psi : w \in \mathbb{C} \longmapsto [e^{w\rho_n(X)}v_n] \in S^2 \setminus \{[v_0]\}$$

is a chart and

$$\chi_2 : [e^{w\rho_n(X)}v_n] \in S^2 \setminus \{[v_0]\} \longmapsto e^{w\rho_n(X)}v_n$$

is a section over $S^2 \setminus \{[v_0]\}$.

The change of coordinates $\psi^{-1} \circ \phi : \mathbb{C} \setminus \{0\} \to \mathbb{C} \setminus \{0\}$ between the charts is

$$w = \psi^{-1} \circ \phi\,(z) = \frac{1}{z}.$$

In fact, we have

$$e^{z\rho_n(Y)}v_0 = \left(1, z, \frac{z^2}{2!}, \ldots, \frac{z^n}{n!}\right) \qquad e^{w\rho_n(X)}v_n = (p_n\,(w)\,, \ldots, p_2\,(w)\,, p_1\,(w)\,, 1)$$

where $p_j\,(w)$ is a polynomial with positive coefficients and $p_1\,(w) = nw$. If $z \neq 0$ then $\left(1, z, \frac{z^2}{2!}, \ldots, \frac{z^n}{n!}\right)$ and

$$\left(\frac{n!}{z^n}, \frac{n!}{z^{n-1}}, \frac{n!}{2!z^{n-2}}, \ldots, \frac{n}{z}, 1\right)$$

span the same line. Hence, if $z, w \neq 0$ then $\left[e^{z\rho_n(Y)}v_0\right] = \left[e^{w\rho_n(X)}v_n\right]$ if and only if $n/z = nw$, which means that $w = 1/z$ as claimed. It follows that $|\psi^{-1} \circ \phi\,(z)\,| = 1$ if $|z| = 1$ so that $S^1 = \{z : |z| = 1\}$ is the same equator of S^2 in both charts.

Now the clutching function $a : S^1 \to \mathbb{C}_\times$ is given by $\chi_2(x) = a(x)\chi_1(x)$ with x in the equator S^1. To get it take $w = \psi^{-1} \circ \phi(z)$. Then

$$\begin{aligned}\chi_2(w) &= e^{w\rho_n(X)}v_0 = \left(\frac{n!}{z^n}, \dots, \frac{n}{z}, 1\right) \\ &= \frac{n!}{z^n}\chi_1(z) = n!w^n\chi_1(z).\end{aligned}$$

Hence, for $x \in S^1$, $a(x) = n!x^n$ which is not homotopic to a point, showing that the bundle is not trivial. $\square$

This proposition implies that the projective orbit $G_1 \cdot [v_0] \approx S^2$ ($G_1 = \langle \exp \rho_n(\mathfrak{sl}(2,\mathbb{C}))\rangle$) in $\mathbb{P}^n$ of the highest weight space is not contractible and hence not contained in an open Bruhat cell. In fact, if the orbit were contractible then the restriction of the tautological bundle on it would be trivial.

The same approach yields also the noncontractibility of the orbits $G_1 \cdot b_k$ on the Grassmannians $\mathrm{Gr}_k(n+1)$, $1 \leq k \leq n-1$, where $b_k = \mathrm{span}\{v_0, \dots, v_{k-1}\}$. To this end we view the Grassmannian $\mathrm{Gr}_k(n+1)$ as a subset of the projective space $\mathbb{P}\left(\wedge^k\mathbb{C}^{n+1}\right)$ of the k-fold exterior power of $\mathbb{C}^{n+1}$. Namely $\mathrm{Gr}_k(n+1)$ is identified to the projective $\mathrm{Sl}(n+1,\mathbb{C})$-orbit of the highest weight space $[\xi_k] \in \mathbb{P}\left(\wedge^k\mathbb{C}^{n+1}\right)$ where $\xi_k = v_0 \wedge \cdots \wedge v_{k-1}$. Via this identification $G_1 \cdot b_k$ is identified to the projective orbit of G_1 through $[\xi_k]$.

Consider the representation of $\mathfrak{sl}(2,\mathbb{C})$ on $\wedge^k\mathbb{C}^{n+1}$ obtained by composing the representation of $\mathrm{Sl}(n+1,\mathbb{C})$ with ρ_n. Denote it by ρ_n as well. Let

$$V_k = \mathrm{span}\{\rho_n^j(Y)\xi_k : j \geq 0\}$$

be the $\mathfrak{sl}(2,\mathbb{C})$-irreducible subspace of $\wedge^k\mathbb{C}^{n+1}$ that contains ξ_k. Since $\rho_n(X)\xi_k = 0$ and ξ_k is an eigenvector of $\rho_n(H)$ with eigenvalue λ we have $\dim V_k = \lambda + 1$. Now, λ is the sum of the k-largest eigenvalues of the matrix $\rho_n(H)$, that is,

$$\lambda = \sum_{j=0}^{k-1}(n-2j) = k(n-(k-1)) > 0.$$

Hence $\dim V_k > 0$ and the $\mathfrak{sl}(2,\mathbb{C})$ representation on V_k is the non trivial irreducible representation ρ_m with $m = k(n-k+1)$.

Now it is clear that the projective orbit $S^2 = G_1 \cdot [\xi_k]$ is contained in the projective space $\mathbb{P}(V_k)$. By Proposition 5.2 we have that the restriction to $G_1 \cdot [\xi_k]$ of the tautological bundle $V_k \setminus \{0\} \to \mathbb{P}(V_k)$ is not trivial. But the tautological bundle of $\mathbb{P}(V_k)$ is the restriction to it of the tautological bundle of $\mathbb{P}\left(\wedge^k \mathbb{C}^{n+1}\right)$. We conclude that the restriction to $G_1 \cdot [\xi_k]$ of the tautological bundle of $\mathbb{P}\left(\wedge^k \mathbb{C}^{n+1}\right)$ is a nontrivial bundle. Hence the orbit $G_1 \cdot [\xi_k] \approx G_1 \cdot b_k \approx S^2$ is not contractible in $\mathbb{P}\left(\wedge^k \mathbb{C}^{n+1}\right)$. A fortiori it is not contractible in $\mathrm{Gr}_k(n+1)$.

Hence the group $G_1 = \langle \exp \rho_n (\mathfrak{sl}(2,\mathbb{C}))\rangle \subset \mathrm{Sl}(n+1,\mathbb{C})$ falls in the conditions of Proposition 3.2 and Corollary 3.3, concluding the proof of Theorem 5.1.

6 Semi-simple subgroups containing regular elements

We consider here two complex semi-simple Lie algebras $\mathfrak{g}_1 \subset \mathfrak{g}$ such that $\mathfrak{g}_1$ contains a regular real element of $\mathfrak{g}$. That is, if $\mathfrak{g}_1 = \mathfrak{k}_1 \oplus \mathfrak{a}_1 \oplus \mathfrak{n}_1 \subset \mathfrak{g} = \mathfrak{k} \oplus \mathfrak{a} \oplus \mathfrak{n}$ are compatible Iwasawa decompositions then there exists a Weyl chamber $\mathfrak{a}^+ \subset \mathfrak{a}$ such that $\mathfrak{a}_1 \cap \mathfrak{a}^+ \neq \emptyset$. For this case we can apply essentially the same proof of Theorem 5.1 to get analogous semigroup generators of G by subsets containing $G_1 = \langle \exp \mathfrak{g} \rangle$.

Theorem 6.1 *Let $\mathfrak{g}_1 \subset \mathfrak{g}$ be complex semi-simple Lie algebras and suppose that $\mathfrak{g}_1$ contains a regular real element of $\mathfrak{g}$. Let G be a connected Lie group with Lie algebra $\mathfrak{g}$ and put $G_1 = \langle \exp \mathfrak{g} \rangle$. Then a subset $\Gamma \subset G$ generates G as a semigroup provided the group generated by Γ is Zariski dense and $G_1 \subset \Gamma$.*

Before proving the theorem we note that G has finite center because $\mathfrak{g}$ is complex, hence the results on semigroups can be applied to G. Also we can prove the theorem only for G simply connected. For otherwise we have the simply connected cover $\pi : \widetilde{G} \to G$ and Γ generates G if and only if $\pi^{-1}(\Gamma)$ generates $\widetilde{G}$. Hence we assume from now on that G is simply connected.

The proof of the theorem is based on Proposition 5.2. Fix a Weyl chamber $\mathfrak{a}^+ \subset \mathfrak{a}$ such that $\mathfrak{a}_1 \cap \mathfrak{a}^+ \neq \emptyset$. By Corollary 3.3 we are required to prove that in any flag manifold $\mathbb{F}_\Theta$ of G the orbit $G_1 \cdot b_\Theta$ is not contractible where b_Θ is the origin of $\mathbb{F}_\Theta$ defined by means of $\mathfrak{a}^+$.

To this end we realize the flag manifolds of G as projective orbits in irreducible representations of $\mathfrak{g}$. If ω is a dominant weight of $\mathfrak{g}$ (w.r.t $\mathfrak{a}^+$) let ρ_ω be the irreducible representation of $\mathfrak{g}$ with highest weight ω. The space of the representation is denoted by V_ω and the highest weight space is spanned by $v_\omega \in V_\omega$.

Since G is simply connected it represents on V_ω.

It is known that the orbit $G \cdot [v_\omega]$ of the highest weight space in the projective space $\mathbb{P}(V_\omega)$ is a flag manifold of G. Precisely, if Σ is the simple system of roots $\Theta = \{\alpha \in \Sigma : \langle \alpha, \omega \rangle = 0\}$ then $G \cdot [v_\omega]$ equals $\mathbb{F}_\Theta$ as homogeneous spaces.

Our objective is to prove that $G_1 \cdot [v_\omega]$ is not contractible in $G \cdot [v_\omega]$. Clearly it is enough to check that $G_1 \cdot [v_\omega]$ is not contractible in $\mathbb{P}(V_\omega)$. We prove this by applying Proposition 5.2 to a representation of a copy of $\mathfrak{sl}(2, \mathbb{C})$ inside $\mathfrak{g}_1$.

Let Π_1 be the set of roots of $(\mathfrak{g}_1, \mathfrak{a}_1)$. As before if $\alpha_1 \in \Pi_1$ then $H_{\alpha_1} \in \mathfrak{a}_1$ is defined by $\alpha_1(\cdot) = \langle H_{\alpha_1}, \cdot \rangle$. The subspace $\mathfrak{a}_1$ is spanned by H_{α_1}, $\alpha_1 \in \Pi_1$. Since $\mathfrak{a}_1 \cap \mathfrak{a}^+ \neq \emptyset$ and ω is strictly positive on $\mathfrak{a}^+$ it follows that there exists $\alpha_1 \in \Pi_1$ such that $\omega(H_{\alpha_1}) \neq 0$.

We choose α_1 with $\omega(H_{\alpha_1}) \neq 0$ such that α_1 is positive for the chosen compatible Iwasawa decomposition, that is, $(\mathfrak{g}_1)_{\alpha_1} \subset \mathfrak{n}^+$. We denote by $\mathfrak{g}_1(\alpha_1)$ the subalgebra of $\mathfrak{g}_1$ spanned by the root spaces $(\mathfrak{g}_1)_{\pm\alpha_1}$, which is isomorphic to $\mathfrak{sl}(2, \mathbb{C})$, and put $G_1(\alpha_1) = \langle \exp \mathfrak{g}_1(\alpha_1) \rangle \subset G_1$.

To get a representation of $\mathfrak{g}_1(\alpha_1)$ take a generator Y of $(\mathfrak{g}_1)_{-\alpha_1}$ and let $V_\omega(\alpha_1)$ be the subspace spanned by $\rho_\omega(Y)^j v_\omega$, $j \geq 0$. Since $(\mathfrak{g}_1)_{\alpha_1} \subset \mathfrak{n}^+$ and v_ω is a highest weight vector we have $\rho_\omega\left((\mathfrak{g}_1)_{\alpha_1}\right) v_\omega = 0$. Also v_ω is an eigenvector of $\rho_\omega(H_{\alpha_1})$ with eigenvalue $\omega(H_{\alpha_1}) \neq 0$. Hence by the usual construction of the irreducible representations of $\mathfrak{sl}(2, \mathbb{C})$ the subspace $V_\omega(\alpha_1)$ is invariant and irreducible by $\rho_\omega(\mathfrak{g}_1(\alpha_1))$. Since the eigenvector $\omega(H_{\alpha_1}) \neq 0$ we have $\dim V_\omega(\alpha_1) \geq 2$ and we get a nontrivial representation of $\mathfrak{sl}(2, \mathbb{C})$ on $V_\omega(\alpha_1)$. In this representation v_ω is a highest weight vector because $\rho_\omega\left((\mathfrak{g}_1)_{\alpha_1}\right) v_\omega = 0$. A posteriori $\omega(H_{\alpha_1}) = \dim V_\omega(\alpha_1) - 1 > 0$.

Now we can apply Proposition 5.2 to the representation of $\mathfrak{sl}(2, \mathbb{C})$ on $V_\omega(\alpha_1)$ to conclude that the restriction to $G_1(\alpha_1) \cdot [v_\omega]$ of the tautological bundle $V_\omega(\alpha_1) \setminus \{0\} \to \mathbb{P}(V_\omega(\alpha_1))$ is not trivial. This implies, by restricting twice, that the tautological bundle $V_\omega \setminus \{0\} \to \mathbb{P}(V_\omega)$ restricts to a nontrivial bundle on the orbit $G_1(\alpha_1) \cdot [v_\omega]$. Hence the orbit $G_1(\alpha_1) \cdot [v_\omega]$ is not contractible on $\mathbb{P}(V_\omega)$ so that it is not contractible on $\mathbb{F}_\Theta = G \cdot [v_\omega]$. Finally, the orbit $G_1 \cdot [v_\omega]$ is not contractible as well since it contains $G_1(\alpha_1) \cdot [v_\omega]$. By Corollary 3.3 this finishes the proof of Theorem 6.1.

Example: The standard realizations of the classical complex simple Lie algebras of types B_l, C_l and D_l as subalgebras of matrices satisfy the condition of Theorem 6.1 as subalgebras of the appropriate $\mathfrak{sl}(n,\mathbb{C})$. In fact, for C_l and D_l one has Cartan subalgebras of diagonal $2l \times 2l$ matrices $\mathrm{diag}\{\Lambda, -\Lambda\}$ with Λ diagonal $l \times l$, while for B_l the Cartan subalgebra is given by $\mathrm{diag}\{0, \Lambda, -\Lambda\}$. The $\mathfrak{a}_1$ are given by such matrices with real entries. A quick glance to these diagonal matrices shows that in any case $\mathfrak{a}_1$ contains diagonal matrices with distinct eigenvalues, and hence regular real elements of $\mathfrak{sl}(n,\mathbb{C})$, $n = 2l$ or $2l + 1$.
